EXP 14:

Collaborative Git/GitHub Workflow using Fork and Pull Requests

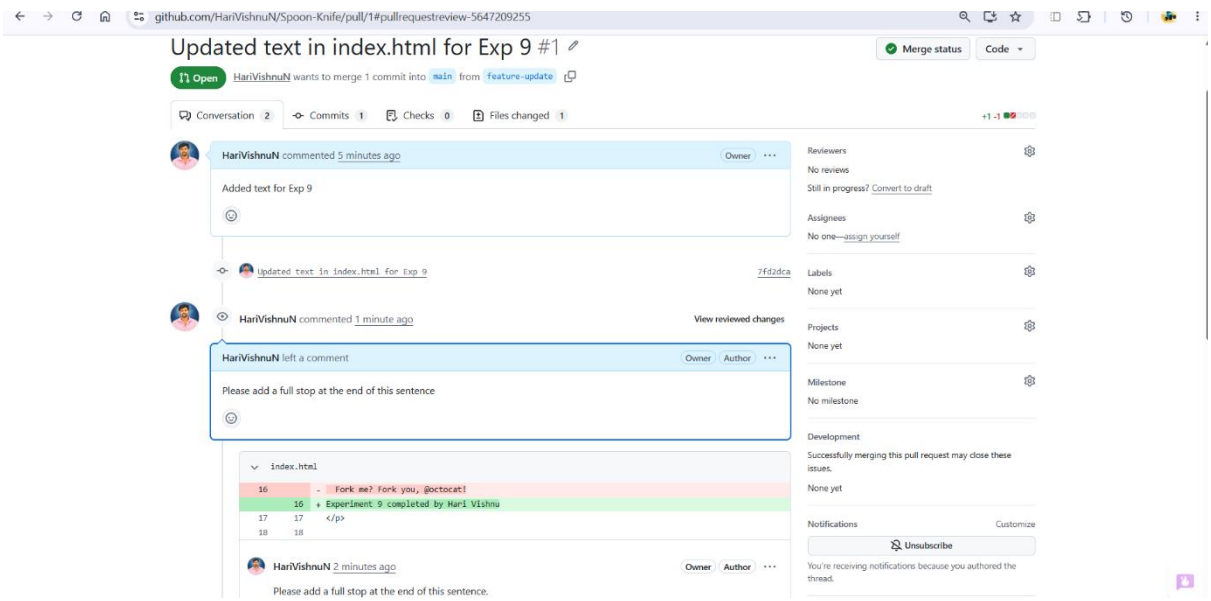

Aim:

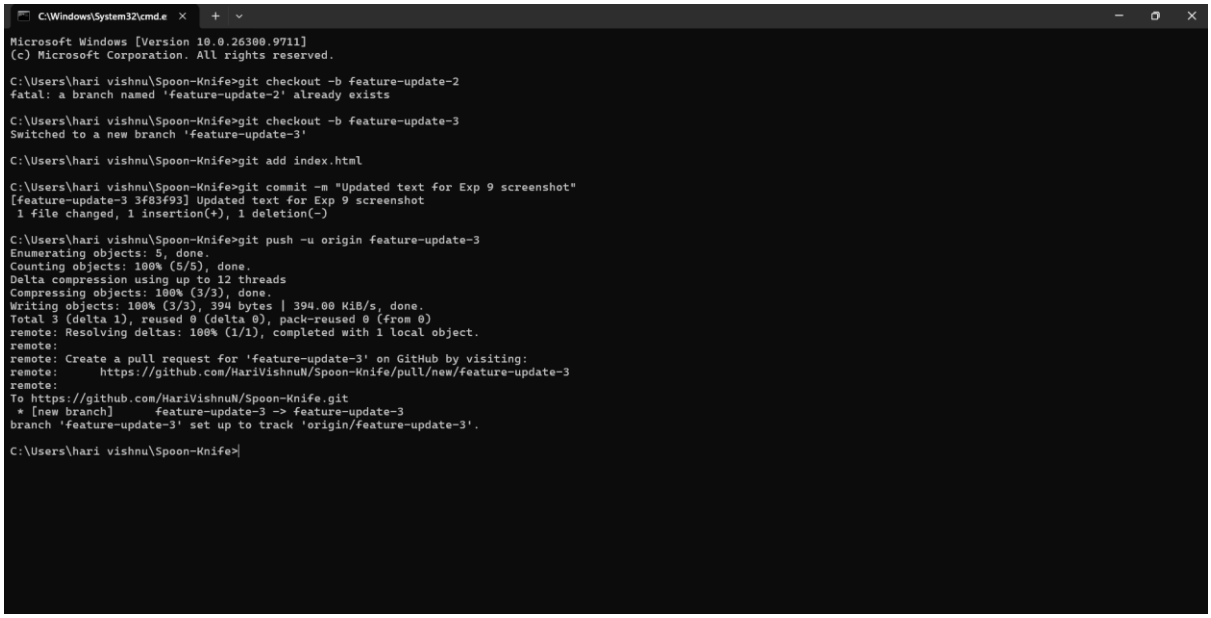

To practice collaborative version control by forking a GitHub repository and submitting a feature branch pull request.

procedure:

1. Fork and Clone: Fork a public repository (e.g., Spoon-Knife) to your own GitHub account, then download it locally using git clone <repository-url>.
2. Create a Feature Branch: Navigate into the project folder and use git checkout -b <branch-name> to create and switch to an isolated branch for your updates.
3. Modify the Code: Open the repository in your code editor, make the necessary changes to a file (like index.html), and save your work.
4. Commit and Push: Save the changes to your branch history using git add <file> and git commit -m "<message>", then upload it to GitHub using git push -u origin <branch-name>.
5. Open a Pull Request: Go to your GitHub repository in the browser and create a Pull Request (PR) to propose merging your feature branch into the main branch.
6. Conduct a Code Review: Go to the PR's "Files changed" tab and simulate a collaborative review by leaving a specific feedback comment on the line you edited.
7. Address Feedback: Return to your local editor to make the requested correction, then commit and push the update to your branch on GitHub.
8. Merge the PR: Once the new commit updates the Pull Request, click "Merge pull request" to integrate the code and finalize the collaborative workflow.

Outputs:

Result: A public repository was forked, modified locally, and pushed through a feature branch. The pull request was successfully reviewed, refined, and merged into the main branch.
